Atomic diffusion in polycrystalline materials is therefore often modeled using an effective diffusion coefficient, which is a combination of lattice, and grain boundary diffusion coefficients. In general, surface diffusion occurs much faster than grain boundary diffusion, and grain boundary diffusion occurs much faster than lattice diffusion.

Atomic diffusion on Si(100) surface was determined by Mo et al. [340, 341] using scanning tunneling microscopy and a link was established between the surface reconstruction and dynamics of atoms; the rate of diffusion in two in-equivalent directions was found to differ by three orders of magnitude. The effects of the substrate on the hetero-epitaxial Ge islands grown on Si (100) substrates
